

# Understanding the Impact of Reaction Conditions on Methanation Catalyst Structure and Performance using in-situ Total Scattering

## Objectives

- Disorder in Ni@g-Al<sub>2</sub>O<sub>3</sub> CO<sub>2</sub> methanation catalysts under dynamic conditions, using Total X-ray scattering, PDF analysis
- Understanding Structural changes, and their impact on catalytic performance

## The Pair Distribution Function

- PDF visually allow visual interpretation of atomic distances as histogram
- Peak width indicates thermal motion; peak height signifies coordination number, overall PDF decay reveals particle size
- Complements conventional XRD analysis; linked through Fourier transform; requiring high Q

## Experimental

- Investigation emulating real world conditions high pressures, up to 12 bar bars, with a focus on: Hydrogen methanation with simulated renewable hydrogen production using drop-out cycles
- 65 KeV ID15a ESRF

## Results

- Achieving a time resolution of 100 ms
- Being able to resolve 2 nm layers of oxide
- First PDF Methanation Last Dropout
- Growth of Ni from 2nm to 6 nm
